The numbers of different neurons in the system are intermediate between small systems like the crustacean stomatogastric ganglion and the spinal cords of fish, amphibia, and reptiles. Five factors make this system exceptionally suitable for computational and experimental investigation of neural mechanisms of coordination .

The crustacean swimmeret system includes a distributed set of local circuits that individually control movements of one jointed limb. These modular local circuits occur in pairs in each segmental ganglion, and normally operate synchronously to produce smoothly coordinated cycles of limb movements on different body segments.

Examining neurogenesis in crayfish is an experimental system that can be easily modified for student labs. A number of different factors have been identified that regulate neurogenesis. Physical activity and environmental conditions have been shown to affect proliferation and survival of neurons in vertebrates (Kemperman and Gage, 1999 ; Van Praag et al., 1999) as well as invertebrates.

Exploring Neurogenesis in Crustaceans

Decapod crustaceans, in particular semiterrestrial crabs, are highly visual animals that greatly rely on visual information. Their responsiveness to visual moving stimuli, with behavioral displays that can be easily and reliably elicited in the laboratory, together with their sturdiness for experimental manipulation and the accessibility of their nervous system for intracellular ...

Control of reproductive development in crustaceans requires neuropeptides, ecdysone and methyl farnesoate (MF). A major source of neuropeptides is the X-organ–sinus gland (XO–SG) complex located in the eyestalk ganglia of crustaceans. The other regulatory factors (either peptides or neuromodulators) are produced in the brain and thoracic ganglia (TG).
